Abstract

We analyse the kinematics of cosmological spacetimes with nonzero torsion, in the framework of the classical Einstein-Cartan gravity. After a brief introduction to the basic features of spaces with non-vanishing torsion, we consider a family of observers moving along timelike worldlines and focus on their kinematic behaviour. In so doing, we isolate the irreducible variables monitoring the observers’ motion and derive their evolution formulae and associated constraint equations. Our aim is to identify the effects of spacetime torsion, and the changes they introduce into the kinematics of the standard, torsion-free, cosmological models. We employ a fully geometrical approach, imposing no restrictions on the material content, or any a priori couplings between torsion and spin. Also, we do not apply the familiar splitting of the equations, into a purely Riemannian component plus a torsion/spin part, at the start of our study, but only introduce it at the very end. With the general formulae at hand, we use the Einstein-Cartan field equations to incorporate explicitly the spin of the matter. The resulting formulae fully describe the kinematics of dynamical spacetimes within the framework of the Einstein-Cartan gravity, while in the special case of the so-called Weyssenhoff fluid, they recover results previously reported in the literature.

1 Introduction

General relativity accounts for the macroscopic distribution of matter. It is therefore reasonable to view Einstein’s theory as the macroscopic limit of a, still illusive, microphysical theory of gravity. The first steps towards such a theory were probably taken by Élie Cartan, who suggested that spacetime torsion could be used as the macroscopic manifestation of the intrinsic angular momentum of the matter \cite{1}. Cartan’s theory, however, was proposed before the discovery of the electron spin and this was perhaps one of the reasons his ideas went essentially unnoticed for some decades. It was probably not until the work of Kibble and Sciama, who laid down the foundations of $U_4$ theory, that the role of spacetime torsion in modern physics was appreciated \cite{2}. Soon after that, a geometrical approach to the new theory was introduced as well \cite{3}.

The Einstein-Cartan gravity, or the Einstein-Cartan-Kibble-Sciama (ECKS) theory as it is sometimes also referred to, is a viable description of the gravitational field that introduces an
additional (rotational) degree of freedom to the spacetime fabric. The latter is carried by the non-
Riemannian (the torsional) component of the affine connection and it is related to the intrinsic
angular momentum (spin) of the matter. By coupling the energy density and the spin of the
matter to the metric and the torsion tensors respectively and by treating them as independent
dynamical variables, the Einstein-Cartan gravity provides the simplest classical extension of
general relativity. The predictions of the theory are essentially indistinguishable from those of
general relativity even at nuclear densities, with departures appearing only at extremely high
densities, like those anticipated in black-hole interiors and the very early universe. In these
environments, the coupling between spin and torsion leads to a repulsive gravitational “force”,
which could (in principle at least) prevent the formation of singularities [4]-[6].

Since its reemergence in the late 1950s, the Einstein-Cartan gravity has gone though several
phases of renewed interest, motivated by the ongoing effort to extend, compare and possibly
link general relativity to the theories of the microphysical interactions. The kinematics of the
theory have been investigated by several authors in an attempt to establish the effects of torsion
and spin, primarily (though not exclusively) on the mean expansion of the Einstein-Cartan
universes [7]-[10]. Almost all of the approaches start by splitting their equations into a purely
Riemannian (general relativistic) part plus a component conveying the effects torsion and spin.
Also, matter is usually represented by the so-called Weyssenhoff fluid, namely an ideal medium
with a specific “equation of state” for the spin density [11]. Here, we do not apply such a
decomposition until the very end of the study. Instead, our kinematic equations (both the
propagation formulae and the constraints) are derived within the full framework of the Riemann-
Cartan geometry. We do so without making any a priori assumptions on the nature of the matter
fields, or specifying the relation between torsion and spin. The effect of the spin is incorporated
in a subsequent step by means of the Cartan field equations. All these imply that our formulae
apply to a general Einstein-Cartan spacetime, with no presumptions about the spin nature. The
latter is specified at the very end of our study, where we also derive the Raychaudhuri equation
of a Weyssenhoff fluid. Our results confirm those of earlier studies, namely that the spin of the
Weyssenhoff medium can inhibit (perhaps even reverse) its gravitational collapse, or assist its
volume expansion. Alternatively, that is for media with non-vanishing spin vector, the effect
of the particles’ intrinsic angular momentum also depends on the “tilt angle” between the spin
vector and the 4-velocity of the fluid.

We begin by briefly outlining how the introduction of torsion alters key features of Riemannian
spaces, such as the operation of covariant differentiation and the interpretation of the
geodesic lines. In the next two sections, we discuss the basic geometric properties of spaces with
nonzero torsion, before proceeding to the so-called Riemann-Cartan spacetimes. Our start-
ing point is the kinematics of timelike worldlines embedded in the aforementioned spacetimes.
This takes place in section 5, where we also provide a direct comparison between the related
Riemannian and Riemann-Cartan (irreducible) kinematics variables. The latter are defined by
employing the so-called 1+3 covariant formalism, which facilitates a geometrical approach that
combines mathematical compactness and clarity with physical transparency. Sections 6 and 7
derive the three evolution and the three constraint equations monitoring the kinematic behaviour
of metric spaces with non-vanishing torsion. These formulae are applied to matter fields with
nonzero intrinsic angular momentum (spin), by employing the Einstein-Cartan and the Cartan
field equations, in section 8. There, we also consider a number of the special cases and among
them that of the Weyssenhoff fluid and re-examine, following an alternative route, how its spin can affect the mean kinematics of the host spacetime.

2 Spaces with torsion

Riemannian geometry demands the symmetry of the affine connection, which means that space has zero torsion by default. Nevertheless, one could treat (classical) torsion as an independent dynamical variable/field, in addition to the metric, and thus “replace” the Riemannian spaces with their more general Riemann-Cartan counterparts.

2.1 The contortion tensor

Consider a general metric space with asymmetric affine connection $\Gamma^a_{bc}$. Demanding the invariance of the metric tensor under covariant differentiation, namely imposing the metricity condition $\nabla_c g_{ab} = 0$, leads to the following expression for the connection

$$\Gamma^a_{bc} = \tilde{\Gamma}^a_{bc} + K^a_{bc}. \quad (1)$$

Here, $\tilde{\Gamma}^a_{bc}$ are the Christoffel symbols of the associated Riemannian space and $K^a_{bc}$ the so-called contortion tensor. The latter is defined by

$$K^a_{bc} = S^a_{bc} + S^a_{bc} + S^a_{bc} = S^a_{bc} + 2S_{(bc)}^a, \quad (2)$$

with $S^a_{bc} = \Gamma^a_{[bc]}$ representing Cartan’s torsion tensor (determined by 24 independent components). Geometrically speaking, the effect of space torsion is to prevent infinitesimal parallelograms from closing (e.g. see [14]). Physically, torsion can provide a possible link between the spacetime geometry and the intrinsic angular momentum (i.e. the spin) of the matter.

Starting from definition (2) and employing some straightforward algebra, one can show that the contortion tensor satisfies the symmetries

$$K_{abc} = K_{[abc]} \, , \quad K_{a(bc)} = 2S_{(bc)} a \, , \quad K_{a[bc]} = S_{abc} \quad (3)$$

and

$$K_{(a|bc)} = -2S_{(ac)b} \, , \quad K_{[a|bc]} = -S_{bac} \, . \quad (4)$$

It follows that, in the special case of a fully antisymmetric torsion tensor (i.e. when $S_{abc} = S_{[abc]}$), the contortion tensor reduces to $K_{abc} = S_{abc}$ and becomes totally skew as well (i.e. $K_{abc} = K_{[abc]}$ – see definition [2] above). The latter, together with relation (3b), ensures that $\Gamma^a_{(bc)} = \tilde{\Gamma}^a_{bc} + 2S_{(bc)}^a \not= \tilde{\Gamma}^a_{bc}$. In other words, the symmetric part of the general connection does not coincide with the Christoffel symbols of the corresponding (torsion-free) Riemannian space.

We finally note that expression (1) also guarantees the invariance of the metric tensor with respect to covariant differentiation in terms of the Levi-Civita connection (i.e. the Christoffel symbols). In other words, in addition to $\nabla_c g_{ab} = 0$, we have $\tilde{\nabla}_c g_{ab} = 0$ as well.

---

1. Throughout this manuscript, tildas will indicate Riemannian variables related to the Christoffel symbols only. We also adopt a spacetime metric with signature $(-, +, +, +)$ and set the speed of light equal to unity.

2. In the literature there are alternative definitions of the torsion and the contortion tensors. Here we follow those of [12], though there the metric signature is $(+, -, -, -)$. Alternatively, one may define the torsion tensor as $S_{bc}^a = \Gamma^a_{[bc]}$ and the contortion tensor as $K_{ab}^c = S_{ab}^c - S_{b}^c a + S_{ab} = S_{ab}^c + 2S_{(ab)}^c$ [13].
2.2 The torsion vector

The antisymmetry of the torsion tensor translates into $S_{ab}^a = -S_{ba}^a$ and $S_{ab}^b = 0$. As a result, there is only one non-trivial contraction of $S_{bc}^a$, which defines the so-called torsion vector

$$S_a = S_{ab}^b = -S_{ba}^b.$$ (5)

It follows that a totally antisymmetric torsion tensor is traceless with zero torsion vector by default. Given that the torsion tensor is trace-free when the torsion vector vanishes and vice-versa, the “modified” torsion tensor

$$\mathcal{S}_{bc}^a = S_{bc}^a + \frac{2}{3} \delta_{[b}^a S_{c]}$$ (6)

is traceless by construction. The contractions of the contortion tensor follow directly from definitions (2) and (5) and they are given by

$$K_{ab}^b = -2S_a, \quad K_{ab}^b = 2S_a \quad \text{and} \quad K_{ba}^b = 0.$$ (7)

Clearly, a totally skew torsion tensor corresponds to a fully antisymmetric and traceless contortion tensor and vice versa.

2.3 Autoparallel and geodesic curves

In metric spaces with non-vanishing torsion, there are two types of preferred curves, namely the autoparallel and the geodesic curves. The former are the “straightest” lines and the latter are the lines of ”extremum” (i.e. minimum/maximum) length [14]. Both reduce to the familiar geodesic curves of the associated Riemannian space when the torsion is switched off.

Consider a curve with parametric equations $x^a = x^a(s)$, where $s$ is an affine parameter and $u^a = dx^a/ds$ is the corresponding tangent vector. By definition the “autoparallel” equation is obtained after imposing the condition of parallel transport along the curve in question, namely by assuming that $u^b \nabla_b u^a = 0$. The latter immediately translates into the autoparallel equation

$$\frac{d^2 x^a}{ds^2} + \Gamma_{bc}^a \frac{dx^b}{ds} \frac{dx^c}{ds} = 0.$$ (8)

Note that only the symmetric part of the connection contributes to the right-hand side of the above, which is however torsion-dependent (see §2.1 previously)

Geodesics are curves of extremal length. Since the distance (i.e. the line element) between any two points depends only on the metric and not on the torsion, the geodesic equation reads

$$\frac{d^2 x^a}{ds^2} + \tilde{\Gamma}_{bc}^a \frac{dx^b}{ds} \frac{dx^c}{ds} = 0.$$ (9)

Exactly as in the associated Riemannian space [14].

Using definition (1), together with the symmetries of the contortion tensor (see Eq. (3b) in §2.1), expression (8) recasts into

$$\frac{d^2 x^a}{ds^2} + \Gamma_{bc}^a \frac{dx^b}{ds} \frac{dx^c}{ds} + 2S_{bc}^a \frac{dx^b}{ds} \frac{dx^c}{ds} = 0.$$ (10)
In the absence of zero torsion, the above immediately reduces to Eq. (9). Moreover, in line with (10), autoparallels and geodesics can coincide even for nonzero torsion, provided that $S_{(ab)c} = 0$. The latter ensures the total antisymmetry of the torsion tensor (i.e. $S_{abc} = S_{[abc]}$), in which case the torsion vector vanishes identically (i.e. $S_a = 0$ – see §2.2 above).

3 Curvature with torsion

Introducing an affine connection different from the Christoffel symbols, means that the geometry of the space is not entirely described by the metric. Instead, the Riemann-Cartan space has additional independent features that are encoded in the torsion/contortion tensor.

3.1 The Riemann-Cartan tensor

The curvature tensor of a general (not necessarily metric) space is obtained from the associated connection, in line with the familiar relation (e.g. see [15])

$$R^a_{bcd} = \partial_c \Gamma^{a}_{bd} - \partial_d \Gamma^{a}_{bc} + \Gamma^{s}_{bd} \Gamma^{a}_{sc} - \Gamma^{s}_{bc} \Gamma^{a}_{sd} .$$

In a metric space with non-vanishing torsion we have $\Gamma^{a}_{bc} = \tilde{\Gamma}^{a}_{bc} + K^{a}_{bc}$ (see Eq. (1) earlier), which substituted into the right-hand side of the above provides the following expression for the Riemann-Cartan curvature tensor

$$\tilde{R}^a_{bcd} = \tilde{\Gamma}^a_{bd} K^a_{sc} + K^a_{bd} \tilde{\Gamma}^a_{sc} - \tilde{\Gamma}^s_{bc} K^a_{sd} - K^s_{bc} \tilde{\Gamma}^a_{sd},$$

where

$$\tilde{\Gamma}^a_{bd} = \partial_c \tilde{\Gamma}^a_{bc} - \partial_d \tilde{\Gamma}^a_{bc} + \tilde{\Gamma}^s_{bd} \tilde{\Gamma}^a_{sc} - \tilde{\Gamma}^s_{bc} \tilde{\Gamma}^a_{sd} ,$$

is the associated (torsion-free) Riemann curvature tensor and

$$Q^a_{bcd} = \partial_c K^a_{bd} - \partial_d K^a_{bc} + K^s_{bd} K^a_{sc} - K^s_{bc} K^a_{sd} .$$

Given the close formalistic analogy between $\tilde{R}^a_{bcd}$ and $Q^a_{bcd}$, the latter may be seen as the purely-torsional counterpart of the Riemann curvature tensor. According to expressions (12)-(14), the curvature tensor of a general space with non-vanishing torsion decomposes into an exclusively Riemannian, a purely torsional and a mixed component.

Nonzero torsion means that the Riemann-Cartan curvature tensor no longer satisfies all the symmetries of its Riemannian counterpart. More specifically, definition (12) and the Ricci identities of a general space with torsion, ensure that $R_{abcd} = R_{[ab][cd]}$ (see footnote 4 in §6 below). In general, however, $R_{abcd} \neq R_{cdab}$ and $R^a_{[bcd]} \neq 0$.

3.2 The Ricci-Cartan tensor

The symmetries of the Riemann-Cartan curvature tensor guarantee that the associated Ricci tensor ($R_{ab} = R_{c=ab}$) remains uniquely defined, despite the presence of torsion. On the other hand, we have $R_{abcd} \neq R_{cdab}$, which implies that the Ricci curvature tensor is not necessarily symmetric (i.e. $R_{[ab]} \neq 0$ – see expression (15) next). Finally, by default, the Ricci scalar ($R = g^{ab}R_{ab}$) remains uniquely defined as well.
The relations between the Ricci tensors and the Ricci scalar of the general space and their torsion-free Riemannian associates are obtained directly from (12). In particular, after taking successive contractions of the latter, arrive at

\[ R_{ab} = \tilde{R}_{ab} + Q_{ab} + \tilde{\Gamma}_{ab}^c K^d_{cd} + K^c_{ab} \tilde{K}^d_{cd} - \tilde{\Gamma}^c_{ad} K^d_{cb} - K^c_{cd} \tilde{\Gamma}^d_{cb} \]  

and

\[ R = \tilde{R} + Q + g^{ab} \tilde{\Gamma}^c_{ab} K^d_{cd} + g^{ab} K^c_{ab} \tilde{\Gamma}^d_{cd} - g^{cb} \tilde{\Gamma}^c_{ad} K^d_{cb} - g^{cb} K^c_{cd} \tilde{\Gamma}^d_{cb} \].  

The former of the above shows that the symmetric part of the Ricci-Cartan tensor does not necessarily coincide with its Riemannian counterpart (i.e. \( R_{(ab)} \neq \tilde{R}_{ab} \) in general).

In an analogous manner, the successive traces of Eq. (14), combined with the definition of the torsion vector (see Eq. (5) in §2.2), lead to

\[ Q_{ab} = \partial_c K^c_{ab} - 2 \partial_b S_a + 2 K^c_{ab} S_c - K^c_{ad} K^d_{cb} \]  

and

\[ Q = g^{ab} \partial_c K^c_{ab} - 2 g^{ab} \partial_b S_a - 4 S_a^a S_a - K_{abc} K^{cab} \].  

Expressions (15)-(18) reveal that the Ricci tensor and the Ricci scalar of the general space split into a solely Riemannian, an entirely torsional and a mixed part.

### 3.3 The Weyl-Cartan tensor

When dealing with Riemannian spaces, the curvature (Riemann) tensor decomposes into its trace (described by the Ricci field) and a traceless component that is commonly referred to as the Weyl tensor. In analogy, the Riemann-Cartan curvature tensor splits as [16]

\[ R_{abcd} = C_{abcd} + R_{a[cg]d} - R_{b[cg]a} - \frac{1}{3} R_{a[cg]d} \].  

The trace-free nature of \( C_{abcd} \), which is straightforward to verify, means that the latter may be seen as the Weyl-Cartan curvature tensor in spacetimes with non-vanishing torsion. Note that, by construction (see definition (19) above), \( C_{abcd} \) also satisfies all the symmetries of the Riemann-Cartan tensor (i.e. \( C_{abcd} = C_{[ab][cd]} \)).

### 3.4 The Bianchi identities

When the space has torsion, the generalised Bianchi identities are also known as the Weitzenbock identities and take the form (e.g. see [17])

\[ \nabla_m R^{ab}_{cd} = 2 R^{ab}_{n[cg]dm} \quad \text{and} \quad R^a_{[bcd]} = -2 \nabla_{[a} S^a_{bc]} + 4 S^a_{m[b} S^m_{cd]} \].  

Contracting the former of the above twice and using the antisymmetry properties of the torsion and the curvature tensors, we arrive at

\[ \nabla^b R_{ba} - \frac{1}{2} \nabla_a R = -2 S^c_{ab} R^{b}_{c} - S^d_{bc} R^{bc}_{da} \].  

When the torsion vanishes, this constraint reduces to the familiar conservation law \( 2 \nabla^b R_{ab} - \nabla_a R = 0 \) of the Riemannian spaces.
4 Spacetimes with torsion

If Riemannian spacetimes are the natural hosts of general relativity, their torsional Riemann-Cartan counterparts provide the geometrical framework for the formulation of perhaps the simplest gravitational theory with intrinsic spin. The latter is usually referred to as the Einstein-Cartan, or sometimes as the Einstein-Cartan-Sciama-Kibble, theory.

4.1 1+3 covariant decomposition

Let us consider a 4-dimensional spacetime equipped with a Lorentzian metric ($g_{ab} = g_{(ab)}$), with $g_{abcd} = g_{[abcd]}$, with signature $(-, +, +, +)$ and introduce a family of observers living along worldlines tangent to the timelike 4-velocity field $u^a$ (normalised so that $u^a u_a = -1$). These observers are associated with a symmetric spacelike tensor $h_{ab} = g_{ab} + u^a u^b$ (with $h_{ab} u^b = 0$, $h_{ab} h^b_c = h_{ac}$ and $h^a_a = 3$). The latter projects orthogonal to the $u^a$-field and essentially defines the metric tensor of the observers' instantaneous 3-dimensional rest-space. On using $u^a$ and $h_{ab}$, one can introduce an irreducible 1+3 splitting of the spacetime into time (along the $u^a$-field) and 3-space (orthogonal to $u^a$). Then, every variable, every operator and every equation can be decomposed into their timelike and spacelike parts.

The totally antisymmetric Levi-Civita tensor of the 4-D spacetime ($\eta_{abcd} = \eta_{[abcd]}$, with $\eta_{abcd} \eta_{mnpq} = -4! \delta^m_a \delta^n_b \delta^p_c \delta^q_d$) splits as

$$\eta_{abcd} = 2u^a \varepsilon_b^c d - 2 \varepsilon_{abc} u^d,$$

with $\varepsilon_{abc} = \eta_{abc} u^d$ representing the alternating tensor of the 3-D space. Then, it follows that $\varepsilon_{abc} = \varepsilon_{[abc]}$, that $\varepsilon_{abc} u^c = 0$ and that

$$\varepsilon_{abc} \varepsilon_{dmn} = 3! h^d_{[a} h^m_{b} h^n_{c]}.$$

Accordingly, $\varepsilon_{abc} \varepsilon_{dmc} = 2 h^d_{[a} h^m_{b]}$, $\varepsilon_{abc} \varepsilon_{dbc} = 2 h^d_{[a}$ and $\varepsilon_{abc} \varepsilon_{abc} = 6$.

4.2 Temporal and spatial gradients

Once a family of observers has been introduced and the spacetime has been split into time and 3-D space, the temporal and spatial derivatives of a general tensor field $T_{ab\cdots} = T_{ab\cdots}(x^s)$ are defined by

$$\dot{T}_{ab\cdots} = u^m \nabla_m T_{ab\cdots},$$

and

$$D_m T_{ab\cdots} = h^q_m h^f_{a} h^k_{b} \cdots h^p_r h^d_{c} \cdots \nabla_q T_{f k\cdots r p\cdots},$$

respectively. Note that after applying (25) to the projection tensor, one can easily show that $D_c h_{ab} = 0$. In other words, $h_{ab}$ remains invariant under spatial covariant differentiation.

Using the definition of covariant differentiation and the relation between the general connection and the Christoffel symbols (see Eq. (1) in §2.1) we can obtain the relations between the temporal and the spatial derivatives in the two spaces. For example, in the case of a covariant second-rank tensor, the time derivatives are related by

$$\dot{T}_{ab} = T_{ab} - u^c \left( K^d_{ac} T_{db} + K^d_{bc} T_{ad} \right),$$

where $K_{ab}$ is the torsion tensor.
with the primes denoting time-differentiation in terms of the Christoffel symbols of the associated torsion-free space. Similarly, we find that the relation between the spatial derivatives is

$$D_c T_{ab} = \tilde{D}_c T_{ab} - h_c^f h_a^d h_b^m (K^p_{df} T_{pm} + K^p_{mf} T_{dp}),$$

keeping in mind that the “tildas” always refer to the associated torsionless space. Note that, when applied to the projection tensor, the former of the above two expressions gives

$$\dot{h}_{ab} = h_{ab}^f + 4u^c u^d S_{cd}(a u_b),$$

where we have also used the symmetries of the contortion tensor (see Eqs. (3) and (4) in § 2.1). The latter relation, on the other hand, leads to

$$D_c h_{ab} = \tilde{D}_c h_{ab},$$

which guarantees that $\dot{D}_c h_{ab} = 0$ when $D_c h_{ab} = 0$ and vice-versa. Given that $D_c h_{ab} = 0$ by construction, we deduce that the projector remains invariant under spatial covariant differentiation both in the general space and in its torsion-free (Riemannian) associate. Then, expression (23) guarantees that the 3-D alternating tensor is also covariantly constant (i.e. $D_d \varepsilon_{abc} = 0 = \tilde{D}_d \varepsilon_{abc}$).

Finally, we have $\dot{\varepsilon}_{abc} = 3u_a \varepsilon_{bc} dA^d$, with $A_a = \dot{u}_a$ (see decomposition (30) next).

5 Kinematics with torsion

The kinematics of a timelike congruence, as well as that of the associated observers, are monitored through a set of irreducible variables. These describe the individual aspects of the motion and satisfy a set of propagation and constraint equations that are fully geometrical in nature.

5.1 The irreducible kinematic variables

All the information regarding the kinematic of the aforementioned family of observers is encoded in the gradient of their 4-velocity vector. The latter decomposes in to the irreducible components of the motion according to

$$\nabla_b u_a = D_b u_a - A_a u_b = \frac{1}{3} \Theta h_{ab} + \sigma_{ab} + \omega_{ab} - A_a u_b.$$

In the above, $\Theta = \nabla^a u_a = D^a u_a$ is the volume scalar that monitors the mean separation between the observers’ worldlines. In particular, $\Theta$ describes expansion when it takes positive values and contraction in the opposite case. The volume scalar is typically used to introduce a representative length-scale ($a$) along the observers’ worldlines, defined by $\dot{a}/a = \Theta/3$. In cosmological studies the latter is known as the scale factor and it is directly related to the Hubble parameter (i.e. $\dot{a}/a = H$). The symmetric and trace-free shear tensor $\sigma_{ab} = D_{[b} u_{a]}$, which is spacelike by construction (i.e. $\sigma_{ab} u^b = 0$), reflects kinematic anisotropies. When applied to a fluid element, in particular, the shear describes changes in it shape under constant volume. The antisymmetric vorticity tensor $\omega_{ab} = D_{[b} u_{a]}$ is also spacelike (i.e. $\omega_{ab} u^b = 0$) and monitors the rotational behaviour of the observers’ worldlines. Moreover, the associated vorticity vector $\omega_a = \varepsilon_{abc} \omega^{bc}/2$ (with $\omega_a u^a = 0$, since $\varepsilon_{abc} u^c = 0$) defines the direction of the rotational axis. Finally, $A_a = u^b \nabla_b u_a$ is the 4-acceleration vector, with $A_a u^a = 0$ as well. Also, following § 2.3, the 4-acceleration vanishes when the observers’ worldlines are autoparallel curves.
5.2 Cartan vs Riemannian variables

When confining to the Riemannian (torsion-free) associate of our general space, expression (31) takes the form
\[ \tilde{\nabla}_b u_a = \tilde{D}_b u_a - \tilde{A}_a u_b = \frac{1}{3} \tilde{\Theta} h_{ab} + \tilde{\sigma}_{ab} + \tilde{\omega}_{ab} - \tilde{A}_a u_b, \]
where the tilded variables are defined in a way exactly analogous to that of their non-tilded counterparts. Also, by construction we have \( \tilde{\sigma}_{ab} u^b = 0 = \tilde{\omega}_{ab} u^b = \tilde{A}_a u^a \). Using the symmetries of the contortion tensor (see Eqs. (3) and (4) in § 2.1), the relations between the two sets of variables given in Eqs. (30) and (31) are
\[ \Theta = \tilde{\Theta} + 2 S_a u^a, \quad \sigma_{ab} = \tilde{\sigma}_{ab} - 2 h_{(a}^c h_{b)}^d S_{cdm} u^m - \frac{2}{3} S_c u^c h_{ab}, \]
\[ \omega_{ab} = \tilde{\omega}_{ab} - h_{[a}^c h_{b]}^d S_{mcd} u^m \quad \text{and} \quad A_a = \tilde{A}_a + 2 S_{(bc)} u^b u^c. \]
According to the above relations, when the torsion tensor is fully antisymmetric, we find that \( \Theta = \tilde{\Theta}, \sigma_{ab} = \tilde{\sigma}_{ab}, A_a = \tilde{A}_a \) (since \( S_a = 0 = S_{(ab)c} \) when \( S_{abc} = S_{[abc]} \)) and only \( \omega_{ab} \neq \tilde{\omega}_{ab} \). More specifically, following Eq. (32b), the two volume scalars coincide when the torsion vector vanishes (i.e. when \( S_{a}^{(bc)} \) is traceless – see § 2.2 earlier), or when \( S_a = 0 \) and only \( \omega_{ab} \neq \tilde{\omega}_{ab} \). In general, however, \( \Theta \neq \tilde{\Theta} \) and the same is also true for the shear, the vorticity and the 4-acceleration (i.e. \( \sigma_{ab} \neq \tilde{\sigma}_{ab}, \omega_{ab} \neq \tilde{\omega}_{ab} \) and \( A_a \neq \tilde{A}_a \)). It is also worth pointing out that (32b) and (33) ensure that \( \tilde{\sigma}_{ab} u^b = 0 = \tilde{\omega}_{ab} u^b = \tilde{A}_a u^a \), thus guaranteeing that \( \tilde{\sigma}_{ab}, \tilde{\omega}_{ab} \) and \( \tilde{A}_a \) are spacelike quantities as well. Finally, we note that expression (33b) is consistent with relation (22b), between the time derivatives of the projector, while it provides the relation \( \dot{\epsilon}_{abc} = \dot{\epsilon}_{abc}^f + 6 u_{[a} \tilde{\epsilon}_{bc] d} S_{(af)} u^d u^f \) between the temporal derivatives of the spatial Levi-Civita tensor.

6 Kinematic evolution

With the exception of the 4-acceleration, the time evolution of the kinematic variables defined in the previous section is obtained after applying the Ricci identity to the observers’ 4-velocity vector. In particular, the timelike component of the resulting expression leads to the propagation formulae of \( \Theta, \sigma_{ab} \) and \( \omega_{ab} \), while its spacelike part provides the associated constraints.

6.1 The timelike Ricci identities

In spaces that allow for nonzero torsion, the Ricci identity takes the form (e.g. see [12])
\[ 2 \nabla_b [ c \nabla_b u_a ] = R^d_{abc} u_d - 2 S^d_{bc} \nabla_d u_a, \]
\[ 2 \nabla_b [ c \nabla_b u_a ] = R^d_{abc} u_d - 2 S^d_{bc} \nabla_d u_a. \]

\(^3\) Analogous relations, between the purely Riemannian and the torsional kinematic variables, have been also obtained in [8], though the conventions used there by the authors are generally different from those adopted here.

\(^4\) Throughout this work we assume a non-tilted spacetime. A Lorentz boost of the observers 4-velocity will also affect the irreducible variables of the motion. When the relative velocity between the two frames is non-relativistic, the changes (generally) resemble those seen in Eqs. (32) and (33) above (e.g. see Appendix A2 in [13]).

\(^5\) In a general (not necessarily metric) space with asymmetric connection \( \Gamma^{a}_{bc} \), applying the Ricci identity to an arbitrary contravariant vector \( u^a \) leads to the expression \( 2 \nabla_b [ c \nabla_b u^a ] = - R^a_{dabc} u^d + 2 S^a_{bc} \nabla_c u^a \). When a metric is introduced into the space (with \( \nabla_c g_{ab} = 0 \)), the above relation combines with (31) to give \( R_{abcd} = - R_{abcd} \).
which in the absence of torsion reduces to the more familiar Riemannian expression $2\nabla_i [a \nabla_b] u_c = \tilde{R}_{abcd} u^d$ (given the increased symmetries of the corresponding curvature tensor). Contracting Eq. (34) along $u_c$, using decomposition (30) and employing some fairly straightforward algebra, leads to the intermediate relation

$$
(\nabla_b u_a) = -\frac{1}{9} \Theta^2 h_{ab} - R_{c[ab} u^c u^{d]} - \frac{2}{3} \Theta (\sigma_{ab} + \omega_{ab}) - \sigma_{ca} \sigma_b^c - \omega_{ca} \omega_b^c + 2 \sigma_{c[a} \omega_{b]}^c \\
+ D_b A_a + \frac{2}{3} \Theta u_{(a} A_{b)} + 2 u_{(a} \sigma_{b)c} A^c - 2 u_{[a} \omega_{b]c} A^c - (A_a u_b - A_a A_b) \\
- \frac{2}{3} \Theta S_{abc} u^c + 2 \left( \frac{1}{3} \Theta u_a - A_a \right) u^c u^d S_{cdb} + 2 (\sigma_a^c + \omega_a^c) u^d S_{cdb}.
$$

Substituting into the left-hand side of the above the decomposition of the 4-velocity gradient (into the irreducible kinematic variables – see Eq. (30) in § 5.1) and keeping in mind that $h_{ab} = 2 u_{(a} A_{b)}$, gives

$$
\frac{1}{3} \dot{h}_{ab} + \tilde{\sigma}_{ab} + \tilde{\omega}_{ab} = -\frac{1}{9} \Theta^2 h_{ab} - R_{c[ab} u^c u^{d]} - \frac{2}{3} \Theta (\sigma_{ab} + \omega_{ab}) - \sigma_{ca} \sigma_b^c - \omega_{ca} \omega_b^c + 2 \sigma_{c[a} \omega_{b]}^c \\
+ D_b A_a + 2 u_{(a} \sigma_{b)c} A^c - 2 u_{[a} \omega_{b]c} A^c + A_a A_b \\
- \frac{2}{3} \Theta S_{abc} u^c + 2 \left( \frac{1}{3} \Theta u_a - A_a \right) u^c u^d S_{cdb} + 2 (\sigma_a^c + \omega_a^c) u^d S_{cdb}.
$$

Finally, projecting the latter orthogonal to the $u_a$-field and using the symmetries of the curvature tensor (see § 3.1 earlier), we arrive at

$$
\frac{1}{3} \dot{h}_{ab} + h_{(a} \omega_{b)}^d \tilde{\sigma}_{cd} + h_{[a} \omega_{b]}^d \tilde{\omega}_{cd} = -\frac{1}{9} \Theta^2 h_{ab} - R_{abcd} u^c u^d - \frac{2}{3} \Theta (\sigma_{ab} + \omega_{ab}) \\
- \sigma_{ca} \sigma_b^c - \omega_{ca} \omega_b^c + 2 \sigma_{c[a} \omega_{b]}^c + D_b A_a + A_a A_b \\
- \frac{2}{3} \Theta h_{a} \omega_{b}^d S_{cmd} u^m - 2 A_a u^c u^d h_{b}^m S_{cmd} \\
+ 2 (\sigma_a^c + \omega_a^c) u^d h_{b}^m S_{cmd}.
$$

given that $h_{a} \omega_{b}^d \tilde{\sigma}_{cd} = h_{(a} \omega_{b)}^d \tilde{\sigma}_{cd}$ and $h_{[a} \omega_{b]}^d \tilde{\omega}_{cd} = h_{[a} \omega_{b]}^d \tilde{\omega}_{cd}$. Note that the terms in the first two lines on the right-hand side have direct Riemannian analogues, whereas those in the last two lines are explicitly due to the presence of torsion. Also, the curvature tensor contains a entirely Riemannian, an exclusively torsional and a mixed component (see Eq. (12) in § 2.1 earlier).

Expression (38) governs the full kinematic evolution of observers living in spacetimes with nonzero torsion, without making any prior assumption regarding the nature of the torsion tensor (or about its coupling to the spin of the matter fields). As we will show next, the trace, the projected symmetric trace-free and the projected antisymmetric components of (38) provide the evolution formulae of the volume scalar ($\Theta$), of the shear tensor ($\sigma_{ab}$) and of the vorticity tensor ($\omega_{ab}$) respectively.

When deriving expression (38), one also needs to use the following auxiliary relation

$$
\nabla_b A_a = D_b A_a + \frac{1}{3} \Theta u_a A_b + u_a (\sigma_{bc} - \omega_{bc}) A^c - (A_a u_b) + A_a A_b,
$$

between the gradients of the 4-acceleration vector.
6.2 The Raychaudhuri equation

Taking the trace of Eq. (38), while recalling that \( R_{ab} = R^c_{acb} \), that \( S_{abc} = S_{a[bc]} \) and that \( S^b_{\ b a} = -S_a \), we obtain the expression

\[
\hat{\Theta} = -\frac{1}{3} \Theta^2 - R_{(ab)} u^a u^b - 2 \left( \sigma^2 - \omega^2 \right) + D_a A^a + A_a A^a \\
+ \frac{2}{3} \Theta S_a u^a - 2 S_{(ab)c} u^a u^b A^c - 2 S_{(ab)c} \sigma^{ab} u^c + 2 S_{[ab]} \omega^{ab} u^c ,
\]

(39)

which is the analogue of the Raychaudhuri equation in spaces with nonzero torsion. Note that \( \sigma^2 = \sigma_{ab} \sigma^{ab}/2 \) and \( \omega^2 = \omega_{ab} \omega^{ab}/2 = \omega_a \omega^a \) by definition. Also, only the symmetric part of the Ricci tensor (which is nevertheless torsion-dependent – see Eq. (15) earlier) contributes to Raychaudhuri’s formula. Finally, we should point out that the terms in the first line on the right-hand side of the above have Riemannian analogues (e.g. see § 1.3.1 in [18]), while those in the second line are explicitly due to torsion.

The Raychaudhuri equation is the key formula of gravitational contraction/expansion and it has played a fundamental role in the formulation of the various singularity theorems (e.g. see [19]). In line with Eq. (39), positive terms on the right-hand side of the aforementioned expression inhibit the contraction, or assist the expansion. Negative terms, on the other hand, accelerate the contraction or decelerate the expansion. For example, when the inner product \( S_a u^a \) takes positive values, it tends to speed up the contraction/expansion of a self-gravitating medium. In the opposite case, namely when \( S_a u^a < 0 \), the effect is reversed.

Raychaudhuri’s formula can simplify considerably under certain symmetry conditions. For instance, in the special case of a totally antisymmetric torsion tensor, Eq. (39) reads

\[
\hat{\Theta} = -\frac{1}{3} \Theta^2 - R_{(ab)} u^a u^b - 2 \left( \sigma^2 - \omega^2 \right) + D_a A^a + A_a A^a + 2 S_{abc} \omega^{ab} u^c ,
\]

(40)

given that \( S_a = 0 = S_{(ab)c} = S_{(abc)} \) when \( S_{abc} = S_{[abc]} \). Also, assuming that the worldlines tangent to the \( u_a \)-field are autoparallel curves, the 4-acceleration vanishes identically (i.e. \( A_a = 0 \)). In addition, when the aforementioned autoparallel congruence is also shear-free and irrotational, we may set \( \sigma_{ab} = 0 = \omega_{ab} \) as well. Then, for standard torsion (with \( S_{abc} = S^a_{[bc]} \) and \( S_a \neq 0 \)), expression (39) reduces to

\[
\hat{\Theta} = -\frac{1}{3} \Theta^2 - R_{(ab)} u^a u^b + \frac{2}{3} \Theta S_a u^a ,
\]

(41)

with only the last term having explicit torsional nature. By construction, the above monitors the expansion/contraction rate of spatially homogeneous and isotropic spacetimes, which may be seen as the torsional analogues of the familiar Friedmann-Robertson-Walker (FRW) universes. In that case the torsion vector has to be purely timelike, since otherwise its presence would have destroyed the isotropy of the model’s spatial hypersurfaces. According to (41), when \( 2 \Theta S_a u^a - 3 R_{(ab)} u^a u^b > 0 \), worldline focusing and the initial singularity can be averted.

We also note that when \( S_a \) vanishes, namely when \( S^a_{bc} = \) trace-free – see § 2.2.2 earlier, there are no explicit torsion terms on the right-hand side of the above. Then, the effects of spacetime torsion come solely from the non-Riemannian components of the the Ricci-Cartan tensor (see Eqs. (15), (17) in § 3.2) and those of the volume scalar (see Eq. (32)) in § 5.2. This also true when dealing with a spacelike torsion vector (i.e. for \( S_a u^a = 0 \)).
6.3 Shear and vorticity evolution

The symmetric trace-free and the antisymmetric parts of the general expression (38), provide the respective evolution formulae of the shear and the vorticity tensors in spacetimes with nonzero torsion. In particular we obtain

\[ h_{(a}^c h_{b)}^d \sigma_{cd} = - \frac{2}{3} \Theta \sigma_{ab} - \sigma_{c(a} \sigma_{b)c} - \omega_{c(a} \omega_{b)c} + D_{(b} A_{a)} + A_{(a} A_{b)} - R_{(a}^c h_{b)}^d u_c u_d \]

\[ - \frac{2}{3} \Theta h_{(a}^c h_{b)}^d S_{cdm} u^m - 2 A_{(a} u^c u^d h_{b)}^m S_{cdm} \]

\[ + 2 (\sigma_{(a}^c + \omega_{(a}^c) u^d h_{b)}^m S_{cdm}, \]  

(42)

for the shear and

\[ h_{(a}^c h_{b)}^d \omega_{cd} = - \frac{2}{3} \Theta \omega_{ab} + 2 \sigma_{c(a} \omega_{b)c} + D_{[b} A_{a]} - R_{[a}^c h_{b]}^d u_c u_d - \frac{2}{3} \Theta h_{[a}^c h_{b]}^d S_{cdm} u^m \]

\[ - 2 A_{[a} u^c u^d h_{b]}^m S_{cdm} + 2 (\sigma_{[a}^c + \omega_{[a}^c) u^d h_{b]}^m S_{cdm}, \]  

(43)

for the vorticity. The former of these expressions monitors distortions in the shape of the \( u_a \)-congruence, which occur under constant volume, while the latter governs the rotational behaviour of these worldlines. As with the Raychaudhuri equation before, when dealing with autoparallel curves, all the 4-acceleration terms on right-hand sides of (42) and (43) vanish identically. Also note that, in both of the above, the curvature tensor is given by Eq. (12).

We may analyse the curvature terms on the right-hand side of Eqs. (42) and (43) further, by employing the following the decomposition of the Riemann-Cartan curvature tensor into its Weyl and Ricci parts (see expression (19) in § 3.3 earlier). In particular, keeping in mind the traceless nature of the Weyl tensor, we arrive at

\[ h_{(a}^c h_{b)}^d \sigma_{cd} = - \frac{2}{3} \Theta \sigma_{ab} - \sigma_{c(a} \sigma_{b)c} - \omega_{c(a} \omega_{b)c} + D_{(b} A_{a)} + A_{(a} A_{b)} + \frac{1}{2} h_{(a}^c h_{b)}^d R_{cd} \]

\[ - C_{(a}^c b) u_c u_d \]

\[ + 2 \frac{2}{3} \Theta h_{(a}^c h_{b)}^d S_{cdm} u^m - 2 A_{(a} u^c u^d h_{b)}^m S_{cdm} \]

\[ + 2 (\sigma_{(a}^c + \omega_{(a}^c) u^d h_{b)}^m S_{cdm}, \]  

(44)

and

\[ h_{(a}^c h_{b)}^d \omega_{cd} = - \frac{2}{3} \Theta \omega_{ab} + 2 \sigma_{c(a} \omega_{b)c} + D_{[b} A_{a]} + \frac{1}{2} h_{[a}^c h_{b]}^d R_{cd} - C_{[a}^c b) u_c u_d \]

\[ - \frac{2}{3} \Theta h_{[a}^c h_{b]}^d S_{cdm} u^m - 2 A_{[a} u^c u^d h_{b]}^m S_{cdm} \]

\[ + 2 (\sigma_{[a}^c + \omega_{[a}^c) u^d h_{b]}^m S_{cdm}, \]  

(45)

respectively. An immediate conclusion following from expressions (42)-(45) is that spacetime torsion can source both shear and rotational anisotropies, which is not surprising. We also note that the symmetric and trace-free tensor \( E_{(ab)} = C_{(a}^c b)^d u_c u_d \) seen in Eq. (44) may be interpreted as the electric component of the Weyl tensor in spacetimes with non-vanishing torsion. Then, the symmetry properties \( C_{abcd} = C_{[ab][cd]} \) ensure that \( E_{(ab)} u^a = 0 \). On the other hand, the fact
that $C_{abcd} \neq C_{cdab}$ implies that $E_{[ab]} = C_{[a}^c [b]d} u_c u_d \neq 0$, in contrast to its Riemannian analogue. We also point out that the second-line terms on the right-hand side of Eq. (44) are explicitly due to the presence of spacetime torsion, while the rest have Riemannian analogues. Finally, the Weyl and the Ricci terms seen in (15) are purely torsional with no Riemannian analogues (e.g. compare to Eqs (1.3.4) and (1.3.5) in § 1.3.1 of [18]).

7 Kinematic constraints

The three evolution formulae of the previous section are supplemented by an equal number of constraints. These hold on the observer’s 3-D rest-space and they are obtained after applying the Ricci identity to the 4-velocity vector and taking the spacelike part of the resulting expression.

7.1 The spacelike Ricci identities

Contracting Eq. (34) with the 3-D Levi-Civita tensor gives

$$\varepsilon_{cda} \nabla^c \nabla^d u_b = -\frac{1}{2} \varepsilon_{cda} R_{mb}^{\ \ cd} u^m + \varepsilon_{cda} S^{mcd} \nabla_m u_b .$$

(46)

Substituting decomposition (30) into the above, projecting the resulting expression orthogonally to the $u_a$-field and keeping in mind that $\omega_{ab} = \varepsilon_{abc} \omega^c$, leads to the intermediate relation

$$\frac{1}{3} \varepsilon_{abc} D^c \Theta - \varepsilon_{cda} D^c \sigma^d + (D^c \omega_c) h_{ab} - D_b \omega_a = 2 \omega_a A_b - \frac{1}{2} \varepsilon_{cda} R_{bm}^{\ cd} u^m - \frac{1}{3} \Theta \varepsilon_{cda} h_{bm} S^{mcd}$$

$$- \varepsilon_{cda} \sigma_{bm} S^{mcd} + \varepsilon_{cda} \varepsilon_{bmn} \omega^m S^{n|cd}$$

$$+ \varepsilon_{cda} A_k u_m S^{mcd} ,$$

(47)

where only the left-hand-side terms and the first two on the right-hand side have Riemannian analogues. The above provides the general constraint equation obeyed by the spatial gradients of the kinematic variables on the observers’ instantaneous 3-D rest-space. Taking the trace, the antisymmetric, as well as the symmetric and trace-free component of (47) leads to a scalar, a vector and a (traceless) tensor constraint respectively.

7.2 The scalar constraint

Isolating the trace of expression (47), taking into account the properties of the 3-D Levi-Civita tensor (recall that $\varepsilon_{abc} = \varepsilon_{[abc]}$ and $\varepsilon_{abc} u^c = 0$ – see § 4.1 before), using the definition of the torsion vector (see Eq. (5) in § 2.2) and decomposition (19), leads to the scalar constraint

$$D_a \omega^a = A_a \omega^a + \frac{1}{4} \varepsilon_{abc} u_d C_{d[a}^{bc]} - \frac{1}{6} \Theta \varepsilon_{abc} S^{[abc]} - \frac{1}{2} \varepsilon_{abc} \sigma^{d[a} S_{d}^{bc]} + S_a \omega^a - S_{(ab)c} u^a u^b \omega^c$$

$$+ \frac{1}{2} \varepsilon_{abc} u^d A^{[a} S_{d}^{bc]} ,$$

(48)

which determines the 3-divergence of the vorticity vector in the presence of torsion. Note that, in addition to the torsion terms, the Weyl-curvature term also vanish in Riemannian spaces (since $C_{a[bc]} = 0$ there).
7.3 The vector constraint

Taking the antisymmetric component of Eq. (47), using relation (23) and decomposition (19), while keeping in mind that $D_c h_{ab} = 0$, the traceless nature of the Weyl tensor and setting $\text{curl} v_a = \varepsilon_{abc} D^b v^c$ (for any spacelike vector $v_a$), provides the vector constraint

$$\frac{2}{3} D_a \Theta = D^b \sigma_{ab} - \text{curl} \omega_a - 2 \varepsilon_{abc} A^b \omega^c - h^b_{\alpha} R_{cb} u^c + \frac{2}{3} \Theta h^a_{[c} h^d_{b]} S^b_{cd} + 2 h^a_{[c} \sigma^d_{b]} S^b_{cd} - 2 h^a_{[c} \epsilon^d_{b]} m_S^b_{m} \omega^m - 2 h^a_{[c} A^d_{b]} u^m S^b_{md},$$

(49)

which determines the curl of the shear in spacetimes with non-vanishing torsion. Note that the symmetric and trace-free tensor $H_{\langle ab \rangle} = \varepsilon_{cd(a} C_{b)m} c^d u^m / 2$ may be seen as the magnetic component of the Weyl tensor in spacetimes with nonzero torsion and reduces to its standard Riemannian counterpart in a torsion-free environment. In addition, by construction we have $H_{\langle ab \rangle} u^b = 0$. Finally, as in Eq. (49) previously, only the torsion terms on the right-hand side of the above have no Riemannian analogues (e.g. see §1.3.1 in [18]).

7.4 The tensor constraint

Finally, after taking the symmetric and trace-free part of expression (47) and setting $\text{curl} v_{ab} = \varepsilon_{cd(a} D^c v^d_{b)}$ for any spacelike tensor $v_{ab}$, we arrive at the (traceless) tensor constraint

$$\text{curl} \sigma_{ab} = -D_b \omega_a - 2 A_{(a} \omega_{b)} + \frac{1}{2} \varepsilon_{cd(a} C_{b)m} c^d u^m + \frac{1}{3} \Theta \varepsilon_{cd(a} h^m_{b)} S^m_{cd} + \varepsilon_{cd(a} \sigma_{b)m} S^m_{cd} - \varepsilon_{cd(a} \epsilon_{m}^n m_S^m \omega^m |c^d | - \varepsilon_{cd(a} A^d_{b]} u^m S^m_{md}.$$

(50)

which determines the curl of the shear in spacetimes with non-vanishing torsion. Note that the symmetric and trace-free tensor $H_{\langle ab \rangle} = \varepsilon_{cd(a} C_{b)m} c^d u^m / 2$ may be seen as the magnetic component of the Weyl tensor in spacetimes with nonzero torsion and reduces to its standard Riemannian counterpart in a torsion-free environment. In addition, by construction we have $H_{\langle ab \rangle} u^b = 0$. Finally, as in Eq. (49) previously, only the torsion terms on the right-hand side of the above have no Riemannian analogues (e.g. see §1.3.1 in [18]).

Before closing this section, we should emphasise that, so far, our study and our results have been purely geometrical in nature. We have analysed the kinematics of timelike worldlines in spacetimes with nonzero torsion, and derived the associated evolution and constraint equations, without making any prior assumption neither about the material content of our spacetime, nor about the nature of the interaction between the matter and the geometry of the host space. Once the field equations and the material content of the spacetime have been specified, our formulae can be used to describe the kinematics of the associated Einstein-Cartan universe. Also note that, after employing relation (1) and the equations given in §2.3, §3.2, §4.2 and §5.2, one can in principle separate the purely Riemannian from the explicitly torsional part of our kinematic formulae. Finally, in the absence of torsion, the full symmetries of the Riemann and the Weyl tensor are restored. Then, expressions (39)-(45) and (48)-(50) reduce to their standard Riemannian counterparts (see §1.3.1 in [18] for a direct comparison).

8 Einstein-Cartan universes

The Einstein-Cartan gravity, or the Einstein-Cartan-Kibble-Sciama theory, as it is also referred to, is probably the simplest extension of general relativity that also accounts for the spin of the matter. As noted in the introduction, it is a viable theory that is expected to depart significantly from Einstein’s gravity for matter densities well above the nuclear threshold.
8.1 The Einstein-Cartan field equations

In the Einstein-Cartan theory we deal with a set of two field equations: one relating the curvature of the spacetime to the energy density of the material component and another coupling the spacetime torsion to the matter spin. The former maintains the form of its general relativistic counterpart, but without the a priori symmetry of the Ricci and the energy-momentum tensors.

In particular, for zero cosmological constant, the Einstein-Cartan field equations read\(^{[12]}\)

\[
R_{ab} - \frac{1}{2} R g_{ab} = \kappa T_{ab},
\]

(51)

where \(R_{ab}\) and \(R\) are given by \([15]\) and \([16]\) respectively, while \(\kappa = 8\pi G\) and \(T_{ab}\) is the canonical energy-momentum tensor of the matter. Going back to expression \([51]\) we find that \(R = -\kappa T\).

Then, the Einstein-Cartan field equations recast as

\[
R_{ab} = \kappa T_{ab} - \frac{1}{2} \kappa T g_{ab}.
\]

(52)

The canonical spin tensor and the associated spin vector of the matter are related to their corresponding torsion tensor and vector though the so-called Cartan field equations, namely\(^{[12]}\)

\[
S_{abc} - S_b g_{ca} + S_c g_{ab} = -\frac{1}{2} \kappa s_{bca} \quad \text{and} \quad S_a = -\frac{1}{4} \kappa s_a.
\]

(53)

We remind the reader that \(S_a = S^b_{\ a} = -S^b_{\ ba}\) (see \(\S\ 2.2\) earlier). Also, \(s_a = s^b_{\ ba} = -s^b_{\ ab}\) defines the canonical spin vector. On using the latter of the above expressions, the Cartan field equations (i.e. expression \([53a]\)) assume the alternative form\(^7\)

\[
S_{abc} = -\frac{1}{4} \kappa (2s_{bca} + g_{ca} s_b - g_{ab} s_c).
\]

(57)

Note that, in line with Eq. \([53a]\), a vanishing torsion vector implies that \(S_{abc} = -\kappa s_{bca}/2\), which guarantees that the spin vector also vanishes. Moreover, when dealing with a totally antisymmetric torsion tensor (with \(S_a = 0\) as a result), we have \(S_{abc} = -\kappa s_{abc}/2\) to ensure the total antisymmetry of the spin tensor as well.

8.2 Einstein-Cartan kinematics

Starting from the Einstein-Cartan field equations it is straightforward to arrive at the following algebraic relations between the Ricci and the stress-energy tensors

\[
R_{(ab)} u^a u^b = \kappa T_{(ab)} u^a u^b + \frac{1}{2} \kappa T, \quad h^b_{\ a} R_{bc} u^c = \kappa h^b_{\ a} T_{bc} u^c,
\]

\[
h^{[a}_{\ c} h^{b]}_d R_{cd} = \kappa h^{[a}_{\ c} h^{b]}_d T_{cd} \quad \text{and} \quad h^{a}_{\ [c} h^{b]}_d R_{cd} = \kappa h^{a}_{\ [c} h^{b]}_d T_{cd}.
\]

(58)

(59)

\(^7\)In \([12]\), as well in several other papers working on Einstein-Cartan gravity, the metric-signature convention is \((+,-,-,-)\). The transformation rules between the two signatures for the key tensors and operators are:

\[
g_{ab} \rightarrow -g_{ab}, \quad u_a \rightarrow -u_a, \quad h_{ab} \rightarrow -h_{ab}, \quad \eta_{abcd} \rightarrow \eta_{abcd},
\]

\[
\partial_a \rightarrow \partial_a, \quad \nabla_a \rightarrow \nabla_a, \quad S^a_{\ bc} \rightarrow S^a_{\ bc}, \quad R_{abcd} \rightarrow -R_{abcd}, \quad T_{ab} \rightarrow T_{ab}, \quad s_{ab} \rightarrow -s_{ab}.
\]

(54)

(55)

(56)

Note that the transformations of the metric tensors (see \([53a]\) and \([53b]\)) ensure that raising an lowering indices changes the sign of the quantities involved (e.g. \(R_{ab} \rightarrow R_{ab}, \ R \rightarrow - R, \ S_{abc} \rightarrow - S_{abc}, \) etc. – see also \([10]\)).
Similarly, the Cartan field equations lead to auxiliary relations between torsion and spin. For example, employing (57), the scalars $S_a u^a$, $S_{(ab)c} u^a u^b A^c$, $S_{(ab)c} \sigma^{ab} u^c$ and $S_{(ab)c} \omega^{ab} u^c$ found on the right-hand side of Raychaudhuri’s formula (see Eq. (39) in §6.2) can be replaced by

$$
S_a u^a = -\frac{1}{2} \kappa s_a u^a, \quad S_{(ab)c} u^a u^b A^c = \frac{1}{4} \kappa (2s_{a(bc)} A^a u^b u^c - s_a A^a),
$$

$$
S_{(ab)c} \sigma^{ab} u^c = \frac{1}{2} \kappa s_{a(bc)} u^a \sigma^{bc} \quad \text{and} \quad S_{(ab)c} \omega^{ab} u^c = -\frac{1}{2} \kappa s_{a(bc)} u^a \omega^{bc}.
$$

This way one can replace the torsion terms in the rest of the kinematic formulae given in §6 and §7 with spin-related variables. Overall, using the Einstein-Cartan and the Cartan field equations, all the geometrical (i.e. the curvature and the torsion) quantities are replaced with matter variables.

Substituting (58), together with the auxiliary relations (60) and (61), into the right-hand side of (39) leads to the Raychaudhuri equation of an Einstein-Cartan universe, namely

$$
\dot{\Theta} = -\frac{1}{3} \Omega^2 - \kappa T_{(ab)} u^a u^b - \frac{1}{2} \kappa T - 2 (\sigma^2 - \omega^2) + D_a A^a + A_a A^a
$$

$$\quad - \frac{1}{6} \kappa \Theta s_A u^a + \frac{1}{2} \kappa s_A A^a - \kappa s_{a(bc)} A^a u^b u^c - \kappa s_{a(bc)} u^a \sigma^{bc} - \kappa s_{a(bc)} u^a \omega^{bc}.
$$

The above monitors the volume expansion/contraction of matter with nonzero spin within the framework of the Einstein-Cartan theory, with no restrictions on the nature of the matter fields involved. In fact, simplified versions of expression (62) have been used to investigate the prevention of singularities in isotropic and anisotropic spacetimes with torsion (e.g. see [4]-[6]).

In the case of spatial anisotropy, one should also involve the associated propagation formula of the shear. By means of (59) and the Cartan field equations (see Eq. (44) in §6.3), the latter reads

$$
h_{[a} c h_{b]} d \tilde{\sigma}_{cd} = \frac{2}{3} \Theta \sigma_{ab} - \sigma_{c(a} \sigma_{b)}^c - \omega_{c(a} \omega_{b)}^c + D_{(b} A_{a)} + A_{(a} A_{b)} + \frac{1}{2} \kappa h_{[a} c h_{b]} d T_{cd}
$$

$$\quad - C_{[a} c d u_{c} u_{d} - \frac{1}{3} \kappa \Theta h_{[a} c h_{b]} d u^{m} s_{mdc} - \kappa A_{(a} h_{b)}^c s_{(d)m} u^{d} u^{m} + \frac{1}{2} \kappa A_{(a} h_{b)}^c s_{c}
$$

$$\quad - \frac{1}{2} \kappa s_{c} u^{e} \sigma_{ab} - \kappa (\sigma_{[a} c + \omega_{[a} c) u^{d} h_{b]} m s_{mdc}.
$$

This expression, which shows that the intrinsic angular momentum of the matter acts as a source of shear anisotropy, may also be used to probe the spin implications for the nature of a potential singularity. For example, one could pose the question of whether non-vanishing spin favours pancake-like or cigar-like singularities.

Matter with non-vanishing spin can also trigger vorticity and affect the rotational behaviour of the host spacetime. Indeed, expression (59) and the Cartan field equations transform the vorticity evolution formula (see Eq. (45) in §6.3) into

$$
h_{[a} c h_{b]} d \tilde{\omega}_{cd} = \frac{2}{3} \Theta \omega_{ab} + 2 \sigma_{c[a} \omega_{b]}^c + D_{[b} A_{a]} + \frac{1}{2} \kappa h_{[a} c h_{b]} d T_{cd} - C_{[a} c d u_{c} u_{d}
$$

$$\quad + \frac{1}{3} \kappa \Theta h_{[a} c h_{b]} d u^{m} s_{mdc} - \kappa A_{(a} h_{b)}^m s_{(d)m} u^{c} u^{d} + \frac{1}{2} \kappa A_{(a} h_{b)}^c s_{c}
$$

$$\quad - \frac{1}{2} \kappa s_{c} u^{e} \omega_{ab} + \kappa (\sigma_{[a} c + \omega_{[a} c) u^{d} h_{b]} m s_{mdc}.
$$

16
Note the explicit spin terms on the right-hand side of the above, revealing how the intrinsic angular momentum of the matter can act as a source of spacetime rotation.

The full kinematic description of an Einstein-Cartan universe, in the presence of torsion and spin, also requires the associated constraints. These are obtained from Eqs. (18)-(50) in an analogous way and lead to the following expressions for the scalar constraint

\[
D_a \omega^a = A_a \omega^a + \frac{1}{4} \epsilon_{abc} u_d C^{[abc]} + \frac{1}{12} \kappa \Theta \epsilon_{abc} s^{[abc]} + \frac{1}{4} \kappa \epsilon_{abc} \sigma_d [s^{bc}]^d - \frac{1}{2} \kappa s_{(ab)c} u^a u^b \omega^c - \frac{1}{4} \kappa \epsilon_{abc} u_d A^{[a}_{s^{bc}]^d},
\]

the vector constraint

\[
\frac{2}{3} D_a \Theta = D^b \sigma_{ab} - \text{curl} \omega_a - 2 \epsilon_{abc} A^{b}_{c} \omega^{c} - \kappa h_{a}^{b} T_{cb} \omega^{c} - \frac{1}{3} \kappa \Theta h_{a}^{b} d_{s^{cd}}^{b} - \frac{1}{3} \kappa \Theta h_{a}^{b} s_{b} - \kappa h_{a}^{c} \epsilon_{b}^{d} s_{cd}^{b} + \frac{1}{2} \kappa s_{ab}^{c} d_{s^{cd}}^{b} + \frac{1}{2} \kappa s_{ab}^{c} s_{cd}^{b} - \frac{1}{2} \kappa \epsilon_{abc} s_{b}^{c} - \frac{1}{2} \kappa \epsilon_{abc} \sigma_{b}^{c} m^{s_{cd}} \omega^{m} - \frac{1}{2} \kappa \epsilon_{abc} \sigma_{b}^{c} s_{m}^{d},
\]

and the tensor constraint

\[
\text{curl} \sigma_{ab} = -D_b (\omega_a) - 2 A_{(a} \omega_{b)} + \frac{1}{2} \epsilon_{cd(a} C_{b) m} [c d] u^m - \frac{1}{6} \kappa \Theta \epsilon_{cd(a} h_{b)} m s^{c d m} - \frac{1}{2} \kappa \epsilon_{cd(a} \sigma_{b)} m s^{c d m} + \frac{1}{2} \kappa \epsilon_{cd(a} \sigma_{b)} c s^{d} - \frac{1}{2} \kappa \epsilon_{cd(a} \sigma_{b)} m s^{c d m} + \frac{1}{2} \kappa \epsilon_{cd(a} \sigma_{b)} m s^{c d m} - \frac{1}{2} \kappa \omega_{(a} s_{b)} + \frac{1}{2} \kappa \epsilon_{cd(a} A_{b)} u_m s^{c d m}. \tag{67}
\]

It goes without saying that, in the absence of torsion and spin, Eqs. (62)-(67) reduce to their standard general-relativistic counterparts [18].

### 8.3 Raychaudhuri’s equation in Einstein-Cartan universes

The mean kinematics of an Einstein-Cartan universe, with spacetime torsion and matter spin that obey the associated field equations (see § 8.1 earlier), are monitored by Raychaudhuri’s formula (see Eq. (62) above). As stated in § 6.2, positive terms on the right-hand side of (62) tend to accelerate/decelerate the expansion/contraction of the medium, while negative ones act in the opposite way. We should also note that, in the presence of torsion and spin, the scalar \( T_{(ab)} u^a u^b \) seen on the right-hand side of Eq. (62) is not necessarily positive, namely the weak energy condition does not always apply in Einstein-Cartan universes, even when dealing with otherwise conventional matter.

Raychaudhuri’s formula can simplify considerably under certain conditions. For instance, when the fluid flow-lines are autoparallel curves, the 4-acceleration vanishes identically. If, in addition, the particle worldlines are irrotational and shear-free, expression (62) reduces to

\[
\dot{\Theta} = -\frac{1}{3} \Theta^2 - \kappa T_{(ab)} u^a u^b - \frac{1}{2} \kappa T - \frac{1}{6} \kappa \Theta \Theta_{a} u^a. \tag{68}
\]

Note the last term on the right-hand side of the above, which vanishes when the spin vector is spacelike. When \( s_a \) has a timelike component, on the other hand, the effect of the aforementioned
term depends on whether the fluid is contracting or expanding (i.e. on the sign of $\Theta$) and on the hyperbolic “tilt angle” $\phi$ (with $\sinh \phi = s_a u^a$) between the spin vector and the 4-velocity of the matter fields.

Alternatively, in the special case of totally antisymmetric torsion, we have $s_{abc} = s_{[abc]}$ and $s_a = 0$ (see expression (57) in § 8.1), in which case, the associated Raychaudhuri equation reads

$$\dot{\Theta} = -\frac{1}{3} \Theta^2 - \kappa T_{(ab)} u^a u^b - \frac{1}{2} \kappa T - 2 \left( \sigma^2 - \omega^2 \right) + D_a A^a + A_a A^a - \kappa s_{abc} u^a u^{bc}.$$  \hspace{1cm} (69)

Specifying the nature of the matter further, namely introducing an expression for the canonical spin tensor ($s_{abc}$) should generally allow one to evaluate the spin terms on the right-hand side of (68), (69) and thus estimate their effect on the mean kinematics of the fluid in question.

Perhaps the simplest case is the so-called Weyssenhoff fluid [11]. This is a macroscopically continuous medium, which is microscopically characterised by the spin of the matter. The latter is monitored by the antisymmetric spin-density tensor ($s_{ab}$), which is related to the canonical spin tensor by means of (70)

$$s_{abc} = s_{ab} u^c.$$ \hspace{1cm} (70)

while it satisfies the so-called “Frenkel condition”, namely

$$s_{ab} u^b = 0.$$ \hspace{1cm} (71)

In other words, the spin-density tensor is spacelike in the rest-frame of the matter. The above conditions combine to ensure that the canonical spin tensor of Weyssenhoff-type media is trace-free by construction, which in turn guarantees that the canonical spin vector vanishes identically (i.e. $s_a = s_a b = -s_a b = 0$) [3].

The canonical energy-momentum tensor of the Weyssenhoff fluid is that of an an ideal medium, of energy density $\rho$ and isotropic pressure $p$, with an additional contribution from the presence of spin. In particular, following [20], we have

$$T_{ab} = \rho u_a u_b + p h_{ab} - A^c s_{ca} u_b,$$ \hspace{1cm} (72)

which implies that $T_{(ab)} u^a u^b = \rho$ and $T = 3p - \rho$ (as a result of the Frenkel condition – see Eq. (71) above).

Applying relations (70)-(72), together with the associated corollaries to Eq. (69) leads to the Raychaudhuri formula of an Einstein-Cartan spacetime filled with a Weyssenhoff-type medium, namely to

$$\dot{\Theta} = -\frac{1}{3} \Theta^2 - \frac{1}{2} \kappa (\rho + 3p) - 2 \left( \sigma^2 - \omega^2 \right) + D_a A^a + A_a A^a - \kappa s_{abc} u^a u^{bc}.$$ \hspace{1cm} (73)

Formalistically, the latter is identical to its classical general-relativistic counterpart (e.g. see § 1.3.1 in [18]). Nevertheless, there are differences due to the presence of torsion and spin, which

---

8 The presence of 3-dimensional antisymmetric second-rank tensor, which is essentially spacelike vector, defines a preferred spatial direction. This makes the Weyssenhoff fluid incompatible with the Cosmological Principle [22].

9 When dealing with Weyssenhoff-type media, the torsion and the spin-density tensors are related by $S_{abc} = -\kappa u_a s_{bc}/2$, while the associated torsion vector vanishes (combine Eqs. (59), (57) and (70), (71)).
are revealed by appealing to the kinematic relations between a Riemann-Cartan and a purely Riemannian spacetime (see expressions (32) and (33) in §5.2 earlier). When dealing with a Weyssenhoff fluid, the aforementioned relations reduce to

$$\Theta = \tilde{\Theta}, \quad \sigma_{ab} = \tilde{\sigma}_{ab}, \quad \omega_{ab} = \tilde{\omega}_{ab} - \frac{1}{2} \kappa s_{ab}$$

respectively. Consequently, with the exception of the vorticity, the kinematic variables of Weyssenhoff-type media are identical to their general relativistic analogues (see also [8]). Moreover, starting from the definition of covariant differentiation, one can easily verify that \(\dot{\Theta} = \tilde{\dot{\Theta}}\) and \(D_a \tilde{A}^a = \tilde{D}_a \tilde{A}^a\) (recall that primes and tildas indicate purely Riemannian environments).

Substituting all of the above into the right-hand side of (73) leads to the following version of the Raychaudhuri equation of a Weyssenhoff fluid

$$\tilde{\Theta}' = -\frac{1}{3} \tilde{\Theta}^2 - \frac{1}{2} \kappa (\rho + 3p) - 2 (\tilde{\sigma}^2 - \tilde{\omega}^2) + \tilde{D}_a \tilde{A}^a + \tilde{A}_a \tilde{A}^a + \frac{1}{2} \kappa^2 s^2 - \kappa s_{ab} \tilde{\omega}^{ab}. \quad (76)$$

with \(s^2 = s_{ab} s^{ab}/2\) defining the magnitude of the spin-density tensor. The above expression reproduces the relation obtained in [10], when the differences in the metric signature and in the definitions of the vorticity and the spin-density tensors are accounted for. Our result also agrees with the familiar interpretation of an Einstein-Cartan spacetime filled with a Weyssenhoff fluid, as a Riemannian space containing a specific perfect fluid with nonzero spin.\footnote{Following [21], a perfect fluid with nonzero spin that satisfies conditions (70) and (71) in a Riemann-Cartan spacetime, is equivalent to a general-relativistic medium with an effective stress-energy tensor of the form

$$T_{ab} = \left( \rho + \frac{1}{3} \kappa s^2 \right) u_a u_b + \left( p - \frac{1}{2} \kappa s^2 \right) h_{ab} - \frac{1}{2} h^{cd} \tilde{\nabla}_d (s_{ca} u_b + s_{cb} u_a). \quad (77)$$

Substituting the above into the classical Raychaudhuri equation leads to expression (76).}

The quadratic spin-density term on the right-hand side of (76) inhibits the collapse or tends to accelerate the expansion of the Weyssenhoff fluid. Thus, spin and vorticity act in tune, which is intuitively plausible. There is an additional effect as well, through the coupling of these two sources, which can go either way. The effect of the spin is highlighted further if we momentarily adopt the familiar general-relativistic scenario of purely gravitational “forces” acting on an irrotational and shear-free perfect fluid with spin. Then, Eq. (76) reduces to

$$\tilde{\Theta}' = -\frac{1}{3} \tilde{\Theta}^2 - \frac{1}{2} \kappa (\rho + 3p) + \frac{1}{2} \kappa^2 s^2 + \Lambda, \quad (78)$$

where we have momentarily reinstated the cosmological constant (\(\Lambda\)). Thus, qualitatively speaking, the spin term on the right-hand side of the above plays the role of an effective (positive) cosmological constant (when \(s = \text{constant}\)), or that of a quintessence field (when \(s = s(t)\)).
We should note, however, that the spin contribution alone is rather unlikely to affect the late-time evolution of an ever expanding universe. Therefore, spin does not seem a likely substitute for dark energy, or capable of leading to an asymptotically de Sitter final phase (e.g. as that described in [23]). On the other hand, since the spin effects become stronger with increasing density, they could have dominated the early stages of the expansion, or the final stages of a recollapsing universe. More specifically, the inclusion of the spin could in principle allow for a geometrical description of inflation, without the need of scalar fields [12]. Also, when dealing with the purely-gravitational collapse of matter with nonzero spin, expressions (76), (78) – the latter with $\Lambda = 0$ – implies that the particle worldlines will not focus if $\kappa s^2 > \rho + 3p$, in which case the associated singularity (future or past) can be averted.

9 Discussion

To this day, the Einstein-Cartan gravity remains a viable theory and it is still experimentally indistinguishable from general relativity. In fact, Sciama expressed little doubt that, had the electron spin been discovered before 1915, Einstein would have included torsion in his theory. By abandoning the symmetry of the affine connection, Cartan demonstrated that its antisymmetric part, known as torsion, becomes an independent dynamical variable of the spacetime, together with the metric tensor. The source of torsion is the intrinsic angular momentum (the spin) of the matter fields, in analogy with their energy density which gives rise to spacetime curvature.

Once it reemerged, primarily through the work of Kibble and Sciama in the late 1950s, the Einstein-Cartan theory has always maintained a level of attention, since it is probably the simplest and most straightforward classical extension of general relativity. Many studies, especially the earlier ones, looked into the implications of torsion and spin for singularity formation and in particular their avoidance. The majority of the studies, are centered around the Weyssenhoff fluid, namely an ideal medium with nonzero spin that satisfies the so-called Frenkel condition. The latter, however, makes the Weyssenhoff-type media incompatible with the Copernican Principle and therefore puts them at odds with the Einstein-Cartan analogues of the Friedmann universes [22]. Also, most authors start by splitting their equations into a purely general-relativistic component supplemented by a torsion/spin part. Here, instead, we have remained within the general framework of the Einstein-Cartan gravity throughout our analysis. In addition, we have avoided imposing any a priori restrictions on the nature of the matter fields, or on the relation between torsion and spin, until the very end of the study. As a result, our kinematic formulae apply to a general imperfect fluid with nonzero spin.

The evolution and constraint equations have been derived in successive stages, first by incorporating the effect of spacetime torsion and then by including the spin itself. This was achieved by connecting torsion and spin through the standard Einstein-Cartan and the Cartan field equations. Given the generality of our starting formulae, however, alternative (i.e. non-standard) relations between the aforementioned two entities may also be used. Our shear and vorticity evolution formulae show that the intrinsic angular momentum of the matter can act as a source of kinematic anisotropy. One could also employ these equations to investigate further the role of torsion and spin in anisotropic spacetimes with nonzero shear or vorticity (or both). Assuming, for example, that the particle spin is aligned along a given axis of symmetry,
one could investigate its potential implications for the early or the late-time evolution of the host spacetime. The effect of the intrinsic angular momentum of the matter on the vorticity of the fluid, as well as their combined action, can also be probed further. In the present article, we focused on the mean kinematics of an Einstein-Cartan spacetime and derived the associated Raychaudhuri equation. The resulting formula was first applied to an irrotational and shear-free medium with zero 4-acceleration, then to matter with a totally antisymmetric spin tensor and finally to the Weyssenhoff fluid. In the former case, the explicit effect of the particle angular momentum vanishes when the associated spin vector is purely spacelike. Alternatively, when there is a timelike component as well, the decisive factor is the hyperbolic (tilt) angle between the spin vector and the 4-velocity of the matter. Finally, in the case of a Weyssenhoff-type medium, we have recovered the results of earlier studies, namely that spin can in principle inhibit (or even reverse) the gravitational pull of the matter, this time via an alternative route.
